
Development of Non-Opioid Analgesics for Acute Pain

Guidance for Industry

DRAFT GUIDANCE

This guidance document is being distributed for comment purposes only.

Comments and suggestions regarding this draft document should be submitted within 60 days of publication in the *Federal Register* of the notice announcing the availability of the draft guidance. Submit electronic comments to <https://www.regulations.gov>. Submit written comments to the Dockets Management Staff (HFA-305), Food and Drug Administration, 5630 Fishers Lane, Rm. 1061, Rockville, MD 20852. All comments should be identified with the docket number listed in the notice of availability that publishes in the *Federal Register*.

For questions regarding this draft document, contact (CDER) Theresa Wells at 703-380-3900.

5
6 This draft guidance, when finalized, will represent the current thinking of the Food and Drug
7 Administration (FDA or Agency) on this topic. It does not establish any rights for any person and is not
8 binding on FDA or the public. You can use an alternative approach if it satisfies the requirements of the
9 applicable statutes and regulations. To discuss an alternative approach, contact the FDA staff responsible
10 for this guidance as listed on the title page.
11

12
13
14 **I. INTRODUCTION**
15

16 This guidance is written in response to the statutory requirements of section 3001(b) of the
17 Substance Use-Disorder Prevention that Promotes Opioid Recovery and Treatment (SUPPORT)
18 for Patients and Communities Act, which directs the Food and Drug Administration (FDA) to
19 issue or update existing guidance to help address challenges to developing nonaddictive medical
20 products to manage pain. In keeping with the mandate of section 3001(b), and considering the
21 severity of the ongoing opioid crisis, this guidance is also intended to assist sponsors in the
22 development of alternatives to opioids for the management of acute pain. Accordingly, this
23 guidance addresses FDA’s current thinking about three specific topics: development of non-
24 opioid analgesic products for acute pain, labeling claims, and expedited programs as they pertain
25 to this purpose.
26

27 This guidance does not address the management of chronic pain, which will be the focus of a
28 future guidance. This guidance also does not address the development of opioid products.
29

30 The contents of this document do not have the force and effect of law and are not meant to bind
31 the public in any way, unless specifically incorporated into a contract. This document is
32 intended only to provide clarity to the public regarding existing requirements under the law.
33 FDA guidance documents, including this guidance, should be viewed only as recommendations,
34 unless specific regulatory or statutory requirements are cited. The use of the word *should* in
35 Agency guidances means that something is suggested or recommended, but not required.
36
37

38 **II. BACKGROUND**
39

40 FDA is committed to using its authorities to take measures targeted to combat the opioid crisis.
41 In 2017, FDA announced its intention to focus on four priorities, two of which directly relate to
42 this guidance: (1) fostering the development of novel analgesic drugs and (2) decreasing opioid

¹ This guidance has been prepared by the Division of Anesthesiology, Addiction Medicine, and Pain Medicine in the Center for Drug Evaluation and Research at the Food and Drug Administration.

Contains Nonbinding Recommendations

Draft — Not for Implementation

43 analgesic exposure and preventing new addiction.² To address these two priorities, and
44 consistent with our mandate under SUPPORT Act section 3001(b) to issue guidance in this area,
45 FDA is publishing this guidance.

46
47 For context, it is important to set forth FDA’s general understanding of pain and specific
48 definition of acute pain. For the purposes of this guidance, *acute pain* is defined as pain, lasting
49 up to 30 days, typically in response to some form of tissue injury, such as trauma or surgery.³
50

51 This understanding informs the development of this guidance, which describes FDA’s current
52 thinking about three aspects of non-opioid analgesic drug development:
53

- 54 • The drug development program appropriate for a non-opioid analgesic to support an
55 indication for the management of acute pain (“acute pain indication”)
56
- 57 • The availability of claims in labeling of non-opioid analgesic products for acute pain
58 regarding elimination or reduction of opioid use and the data needed to support those
59 claims
60
- 61 • The use of expedited programs to support the development program for non-opioid
62 analgesics to manage acute pain
63

III. DEVELOPMENT OF NON-OPIOID ANALGESICS

A. Non-Opioid Analgesic Product Development for Acute Pain

I. General Considerations

71 Indications for analgesics intended to manage acute pain can be general or specific. A general
72 acute pain indication would reflect the expectation that the product will be effective for most
73 types of acute pain.⁴ The number of adequate and well-controlled clinical trials needed to
74 support a general acute pain indication depends on the mechanism of action of the drug, the
75 populations studied, and the degree to which the available information would support the
76 efficacy across the acute pain settings in which the product would be used. Products with well-
77 established analgesic mechanisms of action may be able to obtain a general acute pain indication
78 when supported by at least two clinical trials, each in a different pain population. For example, a
79 novel nonsteroidal anti-inflammatory drug with two successful clinical trials in postoperative

² See the Opioid Policy Steering Committee web page, available at <https://www.fda.gov/about-fda/office-medical-products-and-tobacco/opioid-policy-steering-committee>.

³ This definition of *acute pain* is consistent with the International Association for the Study of Pain’s definition, which is as follows: “Acute Pain is generally accepted as being of recent onset and limited short duration. It usually has a temporal (follows immediately after surgery/trauma) and causal (has a known cause) relationship to injury or disease. The intensity of acute pain is greatest at the onset of injury, but with healing pain intensity reduces.”

⁴ Because of interindividual differences, a product indicated for general acute pain, and expected to be appropriate to manage many kinds of acute pain, does not mean the product is expected to be effective for every patient.

Contains Nonbinding Recommendations

Draft — Not for Implementation

80 pain, one following bunionectomy and one following herniorrhaphy, may be suitable for a
81 general acute pain indication. In contrast, products with novel mechanisms of action are likely to
82 require clinical trials in more than two different pain populations to support a general acute pain
83 indication. As it is generally not feasible to study all possible populations that fall within a
84 general acute pain indication, it may be necessary to include language in labeling describing the
85 limitations of the indication.

86
87 A specific acute pain indication reflects results from studies in a specific pain population (e.g.,
88 postsurgical analgesia following hernia repair). Some products may be suitable only for specific
89 populations (e.g., topical analgesic for underlying soft tissue injury). A specific pain-type
90 indication generally requires evidence from at least two adequate and well-controlled clinical
91 trials.

92
93 Some sponsors may initially choose to demonstrate effectiveness of a particular drug in a
94 specific pain-type population and then subsequently pursue additional specific indications, or a
95 general indication, with additional trials in other acute pain settings to support broader use. In
96 both of these scenarios, additional patient populations and types of pain can be studied and study
97 results submitted as efficacy supplements to broaden the indication. In many cases, for both
98 additional specific indications or to expand the indication from a specific pain indication to a
99 general indication, one additional adequate and well-controlled efficacy trial may be sufficient.

100

101 2. *Trial Design*

102

103 Clinical trials to support a finding of efficacy for a non-opioid analgesic should be randomized,
104 double-blind, superiority trials. The trials should include repeat-dose design as appropriate.
105 Treatment duration should be based on the pain model used to support the proposed indication
106 sought but should be no fewer than 24 hours for products that are not limited to a single dose.
107 The primary endpoint should be based on the change in pain intensity over a suitable time period
108 based on the pain model used in the trial and the product's expected duration of pain relief;
109 however, the time period assessed does not have to be for the full duration of the pain. After
110 evaluation of the primary endpoint, we recommend continued evaluation of both safety and
111 efficacy, for evidence of sustained effect, which may be relevant to acute pain lasting up to 30
112 days.

113

114 For acute pain, it is common to use an analysis such as the Sum of Pain Intensity Difference
115 (SPID) over a prespecified time period that reflects the expected duration of treatment effect of
116 the product. Demonstrating superiority to a comparator is important in non-opioid analgesic
117 trials because the primary endpoint, pain intensity, can be influenced by study design factors
118 such as the use of rescue medication and placebo effect. As a result, a noninferiority trial
119 showing no difference between analgesic treatments could mean that neither product worked in
120 that study.⁵ Suitable comparators for the superiority study could include placebo or another

⁵ See 21 CFR 314.126(b)(2)(iv) (providing "Similarity of test drug and active control can mean either that both drugs were effective or that neither was effective.") For more information about noninferiority trials, see the guidance for industry *Non-Inferiority Clinical Trials to Establish Effectiveness* (November 2016). We update guidances periodically. For the most recent version of a guidance, check the FDA guidance web page at <https://www.fda.gov/regulatory-information/search-fda-guidance-documents>.

Contains Nonbinding Recommendations

Draft — Not for Implementation

121 analgesic if the new product is expected to be more effective than the comparator analgesic. In
122 some cases, the test treatment and control (placebo or a different analgesic drug) may also be
123 added to background therapy (an “add-on study”). The background therapy could be specified or
124 caregiver selected.

125
126 Protocols should prespecify allowed rescue medications. Depending on the pain condition being
127 studied, rescue medications might include nonsteroidal anti-inflammatory drugs or, in clinical
128 settings in which opioids are typically required for adequate pain relief, opioids may be
129 considered. Protocols should also prespecify the frequency, amount, and threshold of pain at
130 which allowable rescue medication(s) can be administered. This is particularly important in
131 placebo-controlled trials where increased use of rescue medication in the control group may
132 diminish the study drug’s treatment effect, leading to a conclusion of ineffectiveness. The
133 statistical analysis plan should describe how discontinuations caused by inadequate pain control
134 will be handled. The concept of rescue use, including the prospective plan in the effectiveness
135 analysis to assess its use, as well as how the data support the overall indication, is important and
136 is discussed further in section III. A. 3. below, under Secondary Efficacy Endpoints.

137
138 3. *Outcome Measures to Obtain an Acute Pain Analgesic Indication*

139
140 Primary Efficacy Endpoint

141
142 In general, an assessment of pain intensity is the primary outcome measure to establish the
143 efficacy of an analgesic intended to manage acute pain. Efficacy endpoints (e.g., change in pain
144 intensity) in a non-opioid analgesic trial should reflect a direct rating of pain intensity by the
145 subject for all settings in which the subject can communicate in a reliable manner. We
146 recommend using a well-defined and reliable patient-reported outcome measure of the subject’s
147 pain intensity.⁶ The selected instrument should have the subject assess their pain at the time of
148 the assessment (i.e., without using a recall period). Generally, a numerical rating scale is the
149 appropriate measure.

150
151 We recommend that sponsors take frequent pain intensity measurements at preselected time
152 points during the trial to accurately measure the effect of a non-opioid analgesic and that effect
153 over time (e.g., every hour for X number of hours, then every 4 hours for X number of hours).
154 All pain intensity measurements, including at baseline, should be obtained before rescue drug
155 administration. In general, the frequency of pain intensity assessment is greater with initial drug
156 administration, early post-event (e.g., post-injury or surgery), when pain may be more intense.
157 The primary efficacy analysis should compare the SPID between treatments at a prespecified
158 time point that, at a minimum, includes the duration of drug effect, and may extend beyond this
159 duration. For example, a non-opioid analgesic with an expected 4- to 6-hour duration of action
160 might have the primary efficacy analysis performed at 24 hours post-dose (SPID₂₄), but
161 secondary efficacy analyses may also be performed at 6 and 12 hours post dose (SPID₆ and
162 SPID₁₂, respectively) to evaluate pain control during the recommended dosing interval.

163

⁶ For a thorough discussion of patient-reported outcome measures, see the guidance for industry *Patient-Reported Outcome Measures: Use in Medical Product Development to Support Labeling Claims* (December 2009).

Contains Nonbinding Recommendations

Draft — Not for Implementation

164 We discourage using a primary endpoint that is based on pain relief (i.e., decrease in pain) rather
165 than pain intensity (i.e., how bad the pain is), as pain relief scales require subjects to report
166 current pain relative to their prior pain experience and may be influenced by other factors such as
167 concurrent adverse reactions, and may be limited by patients' ability to recall their prior
168 experience of pain. Additionally, sponsors should generally avoid using composite scales that
169 are composed of multiple domains (e.g., pain, function, sleep) as the primary outcome measure
170 in a non-opioid analgesic trial. Such multiple domain scales may be difficult to interpret across a
171 population, as the same change in overall score can be based on differing patterns of response to
172 the individual domain scores. For example, an overall score may be higher at baseline, reflecting
173 poor sleep (with functional consequences), with improvement in the score reflecting
174 improvement in sleep, such as might be seen with a sedating drug that does not provide
175 substantive pain control. Multi-item scales, where the items all relate to pain (e.g., pain at rest or
176 with movement), may be useful depending on the type of pain being studied.

177

178 Secondary Efficacy Endpoints

179

180 Secondary outcome measures are important to fully characterize the efficacy of a non-opioid
181 analgesic and should support the primary efficacy endpoint. These secondary outcome measures
182 include measurement of time to onset of pain relief and time to rescue or request for next dose of
183 the study drug. Other informative secondary outcome measures include assessment of use of
184 rescue medications, physical function, and patient global impression of change of pain.

185

186 To measure time to onset of pain relief, FDA has accepted the “two stopwatch method.” In this
187 method, patients are instructed to stop the first stopwatch when they first perceive any analgesic
188 effect and instructed to stop the second stopwatch when they perceive a meaningful amount of
189 analgesia, which may be translated into a description in labeling of median time to meaningful
190 pain relief. FDA remains open to discussion and consideration of approaches beyond the “two
191 stopwatch method” to assess the time to onset of pain relief, which is particularly important to
192 establish if there is an expectation of rapid onset of action (e.g., intravenous formulation).

193

194 For all acute pain non-opioid analgesic studies, it is particularly important that sponsors record
195 the following information:

196

- 197 • The type and amount of rescue medication used, including dose, frequency, and duration
- 198
- 199 • The time that the study drug or rescue medication was administered
- 200
- 201 • The pain intensity measurements before the rescue medication was used and throughout
- 202 the dosing interval (e.g., evaluating SPID over the course of expected duration of action)
- 203

204

205 Use of rescue medication can inform important properties of the drug and should be carefully
206 considered in the design of the study so as not to jeopardize the validity of the study. A sooner-
207 than-expected first use of rescue medication may suggest that the investigational drug has a
208 delayed onset of pain relief. Time to second use of rescue medication may be informative when
considering dosing interval for the investigational drug and supplement knowledge of the drug's

Contains Nonbinding Recommendations

Draft — Not for Implementation

209 pharmacokinetic properties. If the time to second use of rescue medication is earlier than
210 expected based upon drug exposure, waning efficacy can be considered a potential issue.

211 Endpoints Associated with Reducing or Eliminating Opioid Use

212
213 As discussed further below, total elimination of opioid or a numerical reduction in the number of
214 doses, dose per day, or duration of opioid use may support the efficacy of the investigational
215 drug in alleviating pain. In order to support a clinical benefit of a reduction in opioid use that
216 would be described in labeling, sponsors should demonstrate a direct patient benefit, such as
217 clinically meaningful reduction in the incidence and/or severity of opioid-induced adverse
218 reactions. See section III. B. below.

219 Biomarkers

220
221 FDA is not aware of any biomarkers that are useful in developing pain management products,
222 but we welcome feedback on this issue. If sponsors identify a way to use biomarkers in any
223 aspect of a clinical trial associated with non-opioid analgesics for acute pain, we are interested in
224 engaging on this topic.

225 *4. Safety Considerations—Clinical Trial Elements*

226
227
228 When monitoring safety during clinical trials, sponsors should consider the nature of the drug
229 and the trial population. Sponsors may also need to include subject discontinuation and/or study
230 stopping criteria in protocols, depending on the expected safety profile of a non-opioid analgesic.

231
232 Appropriate assessment of both effectiveness and safety relies on accurate and complete capture
233 of the reason for subject discontinuation. Sponsors should assure that when a subject
234 discontinues study drug or withdraws from the trial that the specific reason is obtained.
235 Investigators should be prompted to provide detailed information, with specific causes rather
236 than report terms such as “other,” “subject request,” “investigator decision,” or other such
237 nonspecific categories. Sponsors also should ensure that case report forms are designed to
238 accurately capture the reason for patient discontinuation.

239
240 The size of the safety database needed to support approval for an acute pain indication depends
241 on a number of factors, including whether the drug is a new molecular entity or a reformulation
242 of an approved drug substance. In addition, a nonclinical safety finding or safety data from early
243 clinical studies suggesting a potential serious adverse reaction may necessitate enlargement of
244 the safety database to better define the safety profile of the proposed product. Safety
245 assessments should continue as appropriate after dosing is completed, with consideration of
246 patient population and setting (i.e., inpatient versus outpatient).

247
248 Early in development, sponsors should discuss safety considerations, including the safety
249 database requirements, with FDA.

250
251
252

Contains Nonbinding Recommendations

Draft — Not for Implementation

253 **B. Potential Claims in Labeling for Non-Opioid Analgesic Products for Acute**
254 **Pain That Eliminate or Reduce Opioid Use and Data Needed to Support**
255 **Those Claims**
256

257 1. *FDA Thinking Regarding Concept of “Opioid-Sparing”*
258

259 Consistent with the feedback of the Anesthetic and Analgesic Drug Products Advisory
260 Committee on November 15, 2018, FDA believes the term “opioid-sparing” as a statement in
261 labeling is unlikely to be sufficiently descriptive to be meaningful. Instead, FDA recommends
262 labeling that more clearly and specifically explains the benefits provided by eliminating or
263 reducing the need for opioid analgesics as discussed in section III. B. 2. below.⁷ For drugs that
264 are already approved and for those that are seeking initial approval, considerations in describing
265 elimination or reduction in the need for opioid analgesics are similar.
266

267 2. *Reductions in the Use of Opioid Analgesics That May Merit Description in*
268 *Labeling*
269

270 There are several ways in which a non-opioid analgesic may show benefit in reducing opioid use
271 that would merit description in labeling:
272

- 273 • Eliminating patient use of opioid analgesics in some or all patients in a pain setting in
274 which use of opioids would typically be required to alleviate pain
275
- 276 • Providing adequate analgesia such that the patient can be discharged from the health care
277 facility without opioid analgesics when patients would be expected to be discharged with
278 opioid analgesics
279
- 280 • Showing a direct patient benefit related to reduced opioid analgesic use, such as a
281 clinically meaningful reduction in opioid-associated adverse reactions or earlier
282 functional recovery (e.g., earlier ability to participate in physical therapy with earlier
283 regain of ambulation)
284

285 In each of these scenarios, data should support a finding that the non-opioid and opioid have
286 comparable effects on pain.
287

288 a. *Product eliminates patient use of opioid analgesics*
289

290 Exposure to an opioid analgesic presents a risk of addiction, misuse, or abuse. In addition to the
291 risk of addiction, opioid use also may cause serious adverse reactions, including overdose, and
292 death. Therefore, a non-opioid analgesic for acute pain that completely eliminates the need for
293 an opioid in a setting in which opioid-level analgesic would be otherwise necessary would have
294 the greatest impact on reducing the risk of opioid addiction. In addition to reducing the risk for

⁷ This view is consistent with feedback provided at the November 15, 2018, Meeting of the Anesthetic and Analgesic Drug Products Advisory Committee. See <https://www.fda.gov/advisory-committees/advisory-committee-calendar/november-15-2018-meeting-anesthetic-and-analgesic-drug-products-advisory-committee-meeting>.

Contains Nonbinding Recommendations

Draft — Not for Implementation

295 the patient, the absence of opioid analgesics in the home lessens access to others in the same
296 residence who may seek opioid analgesics for misuse or abuse.

297
298 If a sponsor can show that a product eliminates the need for an opioid analgesic in a statistically
299 significant number of patients in a setting in which opioids are routinely required for adequate
300 acute pain control, this finding could be sufficient to support description in labeling. In such
301 circumstances, labeling that describes analgesia comparable to or better than the comparator
302 opioid may be appropriate.

303
304 b. Product enables patient discharge without opioid analgesics

305
306 As with products that eliminate opioid use, if a sponsor demonstrates that a non-opioid analgesic
307 product eliminates the need for an opioid to manage acute pain at discharge from a health care
308 facility or other outpatient settings, when opioid use post-discharge is routinely needed, this also
309 could be considered adequate to support description in labeling. Additional assessments after
310 discharge would be required to confirm patients' pain can be managed without opioids.
311 Reducing the supply of prescription opioid analgesics in the home reduces the risks of misuse
312 and abuse by both the patient and others within the home. Labeling that describes these findings
313 may be appropriate.

314
315 c. Product reduces patient exposure to opioid analgesics with direct clinical
316 benefit to the patient

317
318 Apart from discharge by a health care facility without opioids, reduction in dosage and/or
319 duration of opioid use alone is not likely to be adequate to support description in labeling. To
320 include a reduction in opioid use in labeling, the reduction claim should be associated with a
321 direct patient benefit such as (1) reduced time to recovery of function, such as more rapid
322 mobility and/or earlier ability to participate in rehabilitation or other clinically meaningful
323 functional outcomes, or (2) a relevant decrease in opioid-related adverse reactions such as less
324 sedation, fewer gastrointestinal side effects (such as constipation), or other adverse reactions. If
325 these types of clinical benefits are adequately demonstrated in clinical trials, language in the
326 labeling delineating these benefits could be included.

327
328 3. *Data to Support Language in Labeling Describing Clinically Meaningful*
329 *Reductions in Opioid Analgesic Use*

330
331 To support language describing clinically meaningful reductions in opioid analgesic use in
332 product labeling for any of the categories described above, sponsors should provide data from at
333 least two adequate and well-controlled trials. As described in section III. B. 2. above, examples
334 of clinically meaningful outcomes include not requiring opioids for a pain model where opioid
335 use is usually required, or, where use of opioids is still needed, showing reduced opioid dose
336 requirements in concert with either a shortening of time to mobility (e.g., following orthopedic
337 surgery) or a reduction in the frequency of major complications of opioid treatment, such as
338 delirium in an elderly population or a reduction in opioid-related adverse reactions.

339

Contains Nonbinding Recommendations

Draft — Not for Implementation

340 FDA also encourages sponsors to include open-label extensions with follow-up assessment of
341 opioid analgesic utilization (e.g., 30 days after discharge following a surgical procedure) to
342 assess whether patients have been taking opioid analgesics during the period of extension.
343

344 FDA does not recommend observational study designs or exclusive use of electronic health care
345 data (e.g., electronic health record or administrative claims data) to support labeling language
346 describing clinically meaningful reductions in opioid analgesic use. Electronic health care data
347 are not sufficiently able to measure factors that may drive selection of patients for the
348 investigational versus the control treatment. Likewise, routinely collected health care data (e.g.,
349 administrative claims data) are insufficient to ascertain primary endpoints, such as pain control,
350 level of function, actual opioid use, and adverse effects.
351

352 However, incorporating electronic health care data may be useful in other respects. For instance,
353 such data may be valuable (1) in assessing opioid analgesics dispensed at discharge and
354 persistent prescribed opioid analgesic dispensing, (2) in understanding current practices and
355 standards of pain management in specific clinical settings, and (3) in identifying patients who
356 may be eligible for study participation. We remain interested in feedback on ways in which
357 these data could be useful to support the development of non-opioid analgesic products.
358

359 We recognize that we are not addressing all aspects of clinical trial design for products that may
360 reduce the use of opioid analgesics in a way that may merit description in product labeling, and
361 we invite comment on this area of clinical trial design in response to this guidance. We also
362 encourage sponsors of any non-opioid analgesic for acute pain seeking a claim of opioid
363 replacement or reduction in labeling to have early and regular discussions with FDA to help
364 ensure the use of adequate and interpretable assessments of treatment benefits that are consistent
365 with a drug's mechanism of action.
366

C. Expedited Programs

367
368
369 FDA encourages the development of non-opioid analgesic products and novel study designs.
370 Non-opioid analgesic development programs designed to replace or reduce the use of opioid
371 analgesics may be eligible for one or more of FDA's expedited review programs, as applicable.
372 FDA encourages early discussion of products that could eliminate or reduce opioid analgesic use
373 and may be suitable for expedited reviews.
374

375 These expedited programs and their relevant criteria are described in the guidance for industry
376 *Expedited Programs for Serious Conditions—Drugs and Biologics* (May 2014). The applicable
377 expedited programs include fast track, breakthrough therapy, priority review, and accelerated
378 approval. Although each program differs, they all offer some form of expedited review and
379 guidance for sponsors for drug development programs.⁸

⁸ In addition to the programs outlined above, the Breakthrough Devices Program may be available for certain nonaddictive medical products to manage pain. (Federal Food, Drug, and Cosmetic Act § 515B (21 U.S.C. 360e-3)). The Breakthrough Devices Program is a voluntary program for certain medical devices and device-led combination products that provide for more effective treatment or diagnosis of life-threatening or irreversibly debilitating diseases or conditions. The guidance for industry and Food and Drug Administration staff *Breakthrough Devices Program* (December 2018) outlines the criteria for designation as a breakthrough device as well as the policies FDA

Contains Nonbinding Recommendations

Draft — Not for Implementation

380 FDA has not had experience with an analgesic approval based on a surrogate or intermediate
381 endpoint that is reasonably likely to predict clinical benefit, as would be consistent with
382 accelerated approval.⁹ Given that pain intensity is a subjective experience that can only be
383 directly reported by the patient, it is difficult to envision how surrogate or intermediate endpoints
384 could be used to predict analgesic effect. However, consistent with applicable statutory criteria,
385 FDA will consider a non-opioid analgesic's abuse or misuse potential and its risk profile relative
386 to available opioid analgesics to determine if the application qualifies for fast track or
387 breakthrough designation during development, or for priority review upon receipt of the
388 marketing application.

intends to use to implement the program. The considerations set forth in that guidance document apply to FDA's review of devices as nonaddictive methods to manage pain.

⁹ See FD&C Act 506(c) and 21 CFR 314.500 et seq. For drugs granted accelerated approval, postmarketing trials have been required to verify and describe clinical benefit.
